# Chemotherapy

Chemotherapy is a widely used treatment for cancer. It involves the use of drugs to kill cancer cells or stop them from multiplying. These drugs work by targeting rapidly dividing cells, which is a characteristic of cancer cells.

However, because chemotherapy affects both cancerous and healthy rapidly dividing cells in the body, it can lead to side effects such as nausea, hair loss, fatigue, and increased risk of infection. To improve the efficiency and reduce the side effects oncologists often use a combination of medications.

Chemotherapy is often given in cycles, with each cycle consisting of a period of treatment followed by a period of rest to allow the body to recover. The length and frequency of the cycles depend on the specific regimen and the type of cancer being treated.

Chemotherapy can be administered in various ways, including orally or intravenously. When given intravenously, these strong medications may destroy the smaller veins in hands quickly and hence we use Central Lines to administer them in large veins. There are many types of such lines like ChemoPort or Port which can be kept for more than one year or PICC lines which may also last for months. Such lines can also be used for taking blood samples. The initial cost of these lines is offset by the improved comfort, reduced pain and timely treatment.

Chemotherapy can be challenging to undergo due to its side effects, but it remains a cornerstone of cancer treatment and has saved countless lives around the world.

## Exclusions
